Factors Affecting Device Adherence of Patients with Obstructive Sleep Apnea Syndrome in the COVID-19 Pandemic and Normalization Process

COVID-19 Pandemic ve Normalization Sürecinde Obstrüktif Uyku Apne Sendromlu Hastaların Cihaz Uyumunu Etkileyen Faktörler

Abstract

Objective: Obstructive sleep apnea syndrome (OSAS) is a common sleep-related breathing disorder. Continuous positive airway pressure (CPAP) therapy is the most effective OSAS treatment; however, adherence to CPAP therapy is problematic with psychological symptoms and other sleep disorders. We investigated whether a difference existed between device compatibility of patients with OSAS who applied to the sleep outpatient clinic during the Coronavirus disease-2019 (COVID-19) pandemic and normalization process and those who applied during pre-pandemic period.

Materials and Methods: This study was a retrospective study. Patients with OSAS who applied to the sleep disorders center for device control between March 27, 2020 and July 1, 2020 and who used a device for at least one year were included. CPAP adherence time during this period and the same period in 2019 were compared.

Results: This study included 190 patients. Regarding the usage times of the device, the average usage time before the pandemic was 5.3±0.6 hours, whereas after the pandemic, it was 4.5±0.9 hours. The device usage time of 54 patients was over four hours before the pandemic; however, it decreased to under four hours after the pandemic. Regarding insomnia, anxiety, and circadian rhythm disorder, there was a significant difference between patients with adequate device use times and patients with inadequate device use times.

Conclusion: During the COVID-19 pandemic period, additional sleep disorders, such as insomnia, circadian rhythm disorder, nightmare disorder, and psychological problems, like anxiety symptoms, were experienced by patients with OSAS. These added sleep and psychological problems affected the device compatibility of patients with OSAS. Knowing the problems that may arise during the COVID-19 pandemic process and conducting studies on these issues will help patients with OSAS, a risky group, improve device compliance.

Keywords: COVID-19, CPAP adherence, obstructive sleep apnea, pandemic

Gereç ve Yöntem: Araştırmaımız retrospektif olgu-kontrol çalışması olup çalışmaya 27.03.2020-01.07.2020 tarihleri arasında uyku polikliniğine cihaz kontrolü için başvuran ve en az 1 aylık cihaz kullanım süresi olan 190 OUAS hastası dahil edilmiştir. COVID-19 pandemi-normalleşme süreci ile pandemi öncesi dönemdeki ortalamaların karşılaştırılmasıyla嵯красартылmıştır.

Bulgular: Cihaz kullanım sürelerine bakıldığında pandemi öncesi ortalamalar cihaz kullanım süresi 5,3±0,6 saat iken pandemi sonrası ortalamalar cihaz kullanım süresi 4,5±0,9 saatti. Elinde bir cihazın olup olmadığını göre 4 saatin altında düştü. Yeteri cihaz kullanım süreleri olan hastalarla yetersiz cihaz kullanım süresi olan hastalar karteşlenmiştir, araalamda insomni, anksiyete ve sirkadıren ritim bozukluğu açısından anlamlı fark olduğu görüldü.

Anahtar Kelimeler: COVID-19, CPAP uyumu, obstrüktif uyku apne, pandemi
Introduction

Coronavirus disease-2019 (COVID-19) pandemic is a virus outbreak that occurred on December 1, 2019, in China. The transmission rate of the virus increased in mid-January 2020 and spread to the whole world. Pandemic affects both physical health and human psychology, also it affects the mental health and wellbeing of the uninfected community (1,2). Studies previously conducted during severe acute respiratory syndrome (SARS) infection have shown that stress, anxiety, and depressive complaints increased in the general population during the infection process (3). During the SARS-CoV-19 pandemic, it has been shown that daytime functionality and nighttime sleep are affected due to medical or social isolation, adding working remotely at home, distance education at home, decreased social communication, and health-related concerns (4). This situation causes psychiatric illnesses and sleep disorders or the advance of previous disorders.

Obstructive sleep apnea syndrome (OSAS) is the most common sleep-related breathing disorder. This disease is often accompanied by hypertension, diabetes, cardiovascular disease, and obesity. Obstructive apneic events; oxidative stress triggers sympathetic activation and inflammation, leading to the onset and progression of cardiac, vascular, metabolic, and cerebrovascular diseases (5,6). Intermittent hypoxia increases hypoxemic stress and causes reactive oxygen molecules to be released (7). In studies conducted with patients with OSAS, pro-inflammatory cytokines such as TNF-alpha and interleukin (IL)-6, IL-8, high levels of nuclear factor kappa B showed that inflammation plays a role in OSAS (8).

The most effective treatment of OSAS is continuous positive airway pressure (CPAP) therapy. With CPAP treatment, symptoms such as snoring, excessive sleepiness, morning headache, concentration and attention deficit, memory problems, and mood changes improve. There is a decrease in insulin resistance, stroke, hypertension, and cardiovascular disease risks (9). Also, it provides a decrease in traffic accidents and an increase in work efficiency (9). As the rate of CPAP usage, which has such significant effects, increases, its effectiveness increases; it is intended to use more than 4 hours a night (10,11). However, less than half of those use CPAP within the recommended period (12). Compliance with device therapy can be problematic, especially in some groups. It was observed that CPAP compliance decreased in the presence of an additional psychiatric disorder or other sleep disorder (13). Studies in patients with post-traumatic stress disorder (PTSD) have shown the relationship between anxiety and depression and low device compliance (14,15). Insomnia, sleep divisions, and recurrent arousals can affect CPAP compliance (16). Poor sleep quality, nightmares, mask-related problems, claustrophobia are other factors associated with low CPAP compliance. Therefore, psychiatric disorders and sleep disorders arising in the COVID-19 pandemic process are thought to affect CPAP compliance. Stopping PAP titration device usage during a pandemic may cause both psychological and physical changes during social isolation. However, it is very important to continue to use PAP titration effectively, especially in people with an increased workload, who continue driving a car and working with the device during a pandemic (17).

In our study, we aimed to investigate whether there is a difference in device compatibility of the OSAS patients who applied to the sleep outpatient clinic during the COVID-19 pandemic and normalization process compared to the pre-epidemic period.

Materials and Methods

This retrospective study was performed at the Sleep Disorders Center of the University of Health Sciences Turkey, Erenköy Mental and Neurological Diseases Training and Research Hospital. All study procedures were approved by the Local Ethics Committee and are compliant with the Declaration of Helsinki (no: 25, date: 06.07.2020). Because the study was retrospective, informed consent was not obtained from patients, but patient identification information was hidden.

In sleep disorders outpatient clinic, all of the admitted patients with the complaints of sleep-related breathing problems fill out Berlin questionnaire (18), the patient health questionnaire-9 (PHQ-9), the general anxiety disorder-7, and PHQ-15 scale (19). These scales are well-established instruments for screening for symptoms of depression, generalized anxiety, and somatization respectively, scores of which 5-9: Mild, 10-14: Moderate, ≥15: Severe anxiety symptoms. In our study, we accepted a score of five and above as the presence of related symptoms. If OSAS is suspected according to answers of Berlin questionnaire, the patients have a full night polysomnography (PSG). The patient who has >5 apnea-hypopnea index (AHI) is diagnosed with OSAS. When AHI >15 or AHI between 5-15 with high Epworth score or additional systemic disease like hypertension, diabetes mellitus etc. or a history of stroke, the patient has a second full night PSG with positive airway pressure (PAP) titration device to determine the appropriate device and pressure. Then the patients are followed at our outpatient clinic for clinical recovery and device adherence periodically.

In this study, we have included the patients who were diagnosed as OSAS according to PSG applied at our sleep disorders center and under treatment with PAP device before pandemic for at least 1 year. We have compared the device adherence of the patients before COVID-19 pandemic and between the date of the first COVID-19 patient diagnosed at 27.03.2020 and the end of the curfew date at 01.07.2020. Patients with OSAS who never used a device or used irregularly or had a device use period of less than 1 year were excluded. Medical records included patients’ age, gender, PSG results, psychiatric symptoms, other sleep disorders, device usage times. CPAP adherence during the same period in the year of 2019 was documented also.

Statistical Analysis

Statistical analysis was performed using SPSS for Windows (version 20.0; SPSS Inc, Chicago, Illinois). The Kolmogorov-Smirnov test was used to determine whether the data were normally distributed. Continuous data were expressed as mean
found in OSAS also. Approximately one-fourth of patients who have had COVID-19 pneumonia and developed intensive care need have a history of OSAS (20). Hypoxemia during sleep in both OSAS and obesity hypoventilation syndrome increases hypoxemia in COVID-19 pneumonia. It is thought that hypoxemia is deeper and cytokine storm develops in OSAS patients, especially accompanied by obesity (7). Furthermore, there are as yet unexplored potential mechanistic links between an imbalance of the angiotensin II receptor and angiotensin II converting enzyme (ACE2) and severe COVID-19 infections, which may also apply in sleep related breathing disorder (21). In OSAS patients, the cytokine storm may worsen COVID-19 pneumonia; acute respiratory distress syndrome (ARDS) and multi-organ failure may develop. ARDS is high in OSAS patients accompanied by obesity (22).

CPAP is an effective treatment of OSAS. Patients who use CPAP for more than 4 hours a night, more than 70% of the days using CPAP, are considered compatible with the treatment (23). However, half of the patients experience device compatibility problems (24). Many factors affect device compatibilities, such as mask problems, the presence of other sleep disorders, and psychological state. It is thought that many situations such as measures taken throughout the country during the COVID-19 pandemic, isolation, quarantine, digital work environments may have directly or indirectly affected device compatibility. In previous studies, low CPAP compliance has been shown in PTSD and additional sleep disorders (25). Different results were found in two studies on device compatibility during the COVID-19 pandemic process. Attias and colleagues evaluated device compatibility in the first month of the COVID-19 pandemic of 7,485 patients with OSAS; the usage time increased from 386 minutes before the pandemic to 401 minutes. They attributed this to conditions such as the fear of hospitalization, staying at home, not being exposed to air pollution, and reduced work stress due to cardiovascular risk factors in most OSAS patients (26). However, Batool-Anwar et al. (27) found no differences in hours of PAP use or self-
reported sleep duration between before and after COVID-19 pandemic. They found that there was an increase in the number of patients with insomnia after the lockdown (27). In our study, the average duration of use, which was 5.3±0.6 hours before the COVID-19 pandemic, decreased to 4.5±0.9 hours after the pandemic.

Researchers in China investigated the psychological effects of the general population in the first phase of the COVID-19 outbreak. They found that 53.8% of respondents rated the psychological impact of the outbreak as moderate or severe, 16.5% reported moderate to severe depressive symptoms, and 28.8% reported moderate to severe anxiety symptoms (28). In our study, it was observed that depressive symptoms, anxiety symptoms, and somatic complaints were added in the COVID-19 pandemic process in OSAS patients. One study examined the relationship between personal social capital scale-16 and sleep quality in individuals who isolated themselves during the COVID-19 outbreak (1). It has been shown that anxiety is associated with stress and decreased sleep quality, and the presence of anxiety and stress reduces the positive effects of social capital on sleep quality. In a study conducted on 1.250 healthcare workers in China, 50.4% of the participants were found to have depression, 44.6% anxiety, and 34.0% insomnia (29). In our study, new insomnia cases were detected during the COVID-19 epidemic period.

Conclusion
In OSAS patients, sleep disorders such as insomnia, circadian rhythm disorder, nightmare disorder, depressive symptoms, and anxiety symptoms were observed during the COVID-19 pandemic period. These added complaints affected the device compatibility of OSAS patients. Being aware of the problems that may arise during the COVID-19 pandemic process and conducting studies on these issues will help the device compliance of patients with OSAS, a risky group.

Ethics
Ethics Committee Approval: This retrospective study was performed at the Sleep Disorders Center of the University of Health Sciences Turkey, Erenköy Mental and Neurological Diseases Training and Research Hospital. All study procedures were approved by the Local Ethics Committee and are compliant with the Declaration of Helsinki (no: 25, date: 06.07.2020).
Informed Consent: Informed consent was not obtained from patients, but patient identification information was hidden.
Peer-review: Externally and internally peer-reviewed.
